

Wk-05-Lab-Overview

Assumptions:

r is the correlation coefficient is how well the data fits a regression line.

Correlation Coefficient (r) Guide

.00-.19 very weak .

.20-.39 weak

.40-.59 moderate

.60-.79 strong

.80-1.0 very strong

Regression Line:

The diagram shows the regression equation $Y_i = \beta_0 + \beta_1 X_i + \epsilon_i$. Labels with arrows point to each term: 'Dependent Variable' points to Y_i , 'Population Y intercept' points to β_0 , 'Population Slope Coefficient' points to β_1 , 'Independent Variable' points to X_i , and 'Random Error term' points to ϵ_i . A blue bracket under $\beta_0 + \beta_1 X_i$ is labeled 'Linear component', and a blue bracket under ϵ_i is labeled 'Random Error component'.

beta_0 - we will rename that to **alpha**

X - is the independent variable that "explains" the movement of Y.

Y - is the dependent variable (and also what we want to 'predict')

Explanation (Review)

β , or **beta** is the slope, or **regression** coefficient. It is a measure of **volatility** relative to a benchmark, such as the S&P 500 (we use the ETF SPY for our X so we are modeling S&P 500)

Investors uses β to asses how risky it is invest in a stock "Y". In essence the investor asses risk by checking the volatility of the symbol with respect to SPY

High β s have **higher risk** and **greater returns**.

Beta Guide:

- $\beta > 1$ **more volatile** than the market (greater than 1)
- $\beta = 1$ **equally** volatile as the market, moves in the **same** direction as the market.
- $0 < \beta < 1$ **less volatile** than the market (e.g, utility companies)
- $\beta = 0$ **unresponsive to** the market (e.g., cash remains at the same value, assuming no inflation).
- $\beta < 0$ **negatively** responsive to the market — or inversely related to market when the market is gaining, stock goes down when the 'market' declines stock does better

Beta in a nutshell: High beta could be good for growth stocks but may be (too) risky.

α , or **alpha** is the intercept - and it is a measure of the **excess return** on an investment in comparison to the market (Y).

In our lab we will assume alpha does not include the error measure, the residual, the noise, or randomness.

Alpha Guide:

- $\alpha > 5$ investor is super great!
- $\alpha > 1$ more profitable than the market (when the market is also profiting)
- $\alpha = 1$ more profitable than the market (by 1% better)
- $\alpha < 1$

Alpha in a nutshell: High alpha is always good.
